ANSWER KEY & EXPLANATORY SOLUTIONS

Comprehensive verified answers, best-practice configs, security controls & reference

VERIFIED SOLUTIONS

A1 AWS CloudFormation addresses a specific

Mitigation

AWS CloudFormation addresses a specific concern—provisioning, configuration management, orchestration, or CI/CD—by automating manual steps that are error-prone, slow, or not reproducible when done by hand.

A6 CI/CD pipelines call AWS CloudFormation in

Observability

CI/CD pipelines call AWS CloudFormation in automated steps: plan on a pull request to preview changes and apply on merge to main. Approval gates can require a human to review the plan before changes go to production.

A2 AWS CloudFormation has a control plane

Primitives

AWS CloudFormation has a control plane that stores desired state and a data plane (agents or push-based SSH) that enforces it. Understanding this distinction clarifies where configuration is evaluated and where changes are applied.

A7 Check AWS CloudFormation's logs for the

Automation

Check AWS CloudFormation's logs for the specific error message and the resource that failed. For infrastructure tools, re-run with increased verbosity (`-v`, `--debug`). Review the state file or event history to understand what changed before the failure.

A3 AWS CloudFormation uses declarative files

Hardening

AWS CloudFormation uses declarative files (YAML, HCL, or a DSL) to express desired state. A plan/diff phase shows what will change before applying. Version-controlling these files enables peer review and rollback.

A8 Rotate credentials used by AWS

Governance

Rotate credentials used by AWS CloudFormation, restrict network access to its control plane, enable audit logging of all operations, and use least-privilege service accounts. Never run AWS CloudFormation with admin credentials in production.

A4 AWS CloudFormation operations are designed to

Gotchas

AWS CloudFormation operations are designed to produce the same result when run multiple times. Applying the same config twice converges to the desired state rather than creating duplicate resources. This makes automation safe to re-run.

A9 Large AWS CloudFormation deployments use

Assessment

Large AWS CloudFormation deployments use workspaces or namespaces to isolate environments, remote state backends for team collaboration, and modular code to avoid a single monolithic config that is slow to plan/apply.

A5 Secrets should never be stored in

Federation

Secrets should never be stored in plain-text in AWS CloudFormation config files. Use a secrets backend (Vault, AWS Secrets Manager) and inject values at runtime via environment variables or encrypted vaults supported by the tool.

A10 Common pitfalls include storing secrets in

Optimization

Common pitfalls include storing secrets in plain-text config, skipping the plan step before apply, not reviewing state drift, and not having a rollback strategy when a deployment fails partway through.
